KYC record check: 5,282 Indian fund records, plus sanctions name screening

Pradeep Rathore · proof of work for Client Data Analyst, KYC Operations (JPMorganChase Asset & Wealth Management, Bengaluru, req. 210788205) · built and run 30 Oct 2026 · code: github.com/Pradeep00777/Kyc-record-

The posting asks the analyst to "review and enhance data collection and verification processes to ensure KYC records are accurate and complete." Bank KYC files are private, so I used the closest public stand-in: the **GLEIF LEI records** banks use as reference data for legal-entity clients, for **every India-domiciled fund** (mutual-fund schemes, AIFs, provident/superannuation/gratuity trusts), screened against the **OFAC SDN list**. Live book: **5,282** LEIs (4,677 issued + 605 lapsed; 757 retired/duplicate excluded).

COMPLETENESS AND CONSISTENCY CHECKS

Check (the question a KYC analyst asks of the record)	Records	Share
C1 LEI lapsed: renewal overdue, so the data is no longer re-validated	605	11.5%
C3 Entity-supplied only: identity never validated against a registry	2,027	38.4%
C4 Sub-scheme linked to neither its umbrella fund nor its manager	204	8.0% of sub-schemes
C6 Entity status blank on an issued LEI	12	0.2%
C7 PIN code inconsistent with state / state missing	3 / 44	0.9%
C10 Same legal name on two live LEIs (possible duplicate records)	5 pairs	0.2%
Records failing at least one check that needs action	**2,420**	**45.8%**

1. **Stale data:** lapsed LEIs are a median **678 days** past renewal; 418 are over a year overdue; 355 of them were also never registry-validated.
2. **Unverified identity sits in trusts:** all 1,288 PF/superannuation/gratuity trusts are entity-supplied only (no public registry exists), so their KYC must rest on the trust deed and trustee documents. Outside them, 739 of 3,994 (18.5%) are still unverified.
3. **Broken ownership chains:** 204 sub-schemes (202 of them AIF sub-schemes) cannot be traced to a controlling party from the record.
4. **Duplicates and errors a rule catches:** *Tata Motors Limited Superannuation Fund* under two issued LEIs; two different LEIs whose whole legal name is "Scheme 1"; *Eximius Fund II* with PIN 122002, city Sikandarpur (Gurugram, Haryana) but state recorded as Gujarat.

SANCTIONS NAME SCREENING: CUTTING FALSE POSITIVES WITHOUT DROPPING REAL HITS

Stage (21,389 OFAC SDN entity names and aliases)	Alerts	Funds alerted
Naive fuzzy match (token-set ≥ 90 after removing legal suffixes)	2,228	1,262 (23.9%)
Two-way distinctive-token guard (Jaro–Winkler ≥ 0.92 on non-generic words, both directions)	18	17
After my review of all 18 (name, entity type, SDN address country)	0 true matches	–99.2% alerts

- Why naive fails: "T C CAPITAL CO LTD" reduces to "CAPITAL" and hits 316 funds; "Z AXIS LLC" (Russia) hits 118 Axis schemes; "SUN AND SUN LIMITED" hits 114 Aditya Birla Sun Life schemes.
- Recall test, 300 random SDN entity names: the guard kept **299/300** exact names (case/punctuation changed), 300/300 with "FUND I" appended, and 273/273 of the one-letter typos the naive matcher caught (naive itself catches only 273/300 typos).

LIMITS, AND WHAT I WOULD DO IN WEEK ONE

Limits: LEI data is reference data, not a KYC file: no ID documents, beneficial owners or transactions, and checks test what a record says, not whether it is true. Screening is OFAC SDN only (no UN/EU/UK/MHA lists, PEP or adverse media); the guard was tuned on this data and the recall test is synthetic; my 18 dispositions used name, entity type and country, where a real review would also compare registration numbers and addresses.

Week one: (1) run the same rules on the team's records ahead of periodic reviews so analysts start from a sorted list (stale, unverified, broken chain, duplicate); (2) measure screening false positives per list and rule, and propose guard rules with a recall test, for Compliance sign-off; (3) track which fields come back from QC and fix the collection step that causes them.

Sources: GLEIF API (api.gleif.org, golden copy 30 Oct 2026); OFAC SDN, ALT and ADD files (treasury.gov/ofac/downloads). Python, rapidfuzz; ~40 s run. All counts reproducible from the code; public data only, no JPMorganChase data used.
